/* The Berkeley UPC Runtime Specification
 * Version: 3.5
 * $Revision: 1.17 $
 * Copyright 2002-4, Dan Bonachea <bonachea@cs.berkeley.edu>
 */

/* This file describes the interface between the platform-independent code
   generated by a UPC-to-C translating compiler, and the hand-written UPC
   runtime layer that implements the language on a given architecture

Many/most of the operations below will be implemented using macros or inline functions in an actual
   implementation (a number of design decisions in the interface were based on the expected optimizations
   that will occur in such an implementation)
They are specified using function declaration syntax below to make the types clear
All correct generated code must type check using the definitions below
In no case should client code assume it can create a "function pointer" to any of these operations

Note this interface is meant primarily as a compilation target for a code generator,
   not a library for hand-written code - as such, the goals of expressiveness and performance
   generally take precedence over readability and minimality

Implementation-specific values in declarations are indicated using "???"
Sections marked "Implementor's note" are recommendations to implementors and are
   not part of the specification
 */

/* UPC Runtime Types
   =====

For more information on a particular type, see the relevant section of the
specification below.

upcr_thread_t           // UPC thread number
upcr_shared_ptr_t       // shared pointer
upcr_pshared_ptr_t      // phaseless shared pointer (indefinitely blocked or blocksize=1)
upcr_phase_t            // phase of shared pointer
upcr_register_value_t   // largest unsigned integer type that will fit in a CPU register
upcr_handle_t           // handle for nonblocking operations
upcr_valget_handle_t    // handle for nonblocking value get operations
upcr_startup_shalloc_t  // Information struct for statically allocated shared data
upcr_startup_pshalloc_t // Information struct for statically allocated, phaseless shared data
upcr_startup_arrayinit_diminfo_t // Initialization info for each dimension of a statically
                                   // allocated shared array
 */

/* ----- */
/* Control Interface
   =====
 */

/*****
 * Runtime initialization functions.
 *
 * There are two sets of initialization functions for the Berkeley UPC
 * runtime: one low-level set targeted at compiler developers, who want the
 * largest amount of control over behavior, and one 'simpler' interface,
 * targeted at application/library developers who wish to use UPC within a
 * larger, non-UPC C/C++ program (though it can also be used by UPC
 * compilers). The simpler interface (bupc_init() and bupc_init_reentrant())
 * uses the lower-level API, plus a set of 'magic' global variables provided
 * by the UPC linker, to provide the full set of information needed, while the
 * low-level API takes all needed information in the function parameters.
 */

/*****
 * Low-level API:
 *
 * If used, the low-level initialization functions must be called in the
 * following order:
 *
 *     upcr_startup_init()
 *     upcr_startup_attach()

```

```

*      upcr_startup_spawn()
*      upcr_exit()          // not always needed: see description
*/

/*
* Bootstraps a UPC job and performs any system-specific setup required.
*
* Called by all applications that use the UPC runtime at startup to bootstrap
* the job before any other processing takes place. Must be called before
* any calls to any other functions in this specification, with the
* command-line parameters passed to main (argc/argv), which may be modified
* or augmented by this call (and are thus not safe to use before this call).
* The semantics of any code executing before the call to
* 'upcr_startup_init()' is implementation-specific (for example, it is
* undefined whether 'stdin/stdout/stderr' are functional, or even how many
* nodes will run that code).
*
* If the application using the runtime requires that it be run with a
* fixed number of UPC threads, pass the thread count in the
* 'static_threadcnt' parameter, and the program will abort with a error
* message if the provided value does not match the execution environment that
* will be provided. Pass <= 0 for applications that can run with a dynamic
* number of UPC threads. If pthreads are used, a positive integer must be
* supplied for 'default_pthreads_per_proc'; otherwise, pass 0.
*
* The 'main_name' parameter should be passed the name of the user's main()
* UPC function: it is used to help users find that symbol name when debugging.
* You may pass NULL if this is not needed.
*
* Upon return from 'upcr_startup_init()', all the nodes of the job will be
* running, stdout/stderr will be functional, and the basic job environment
* will be established, however the primary network resources may not yet have
* been initialized. The following runtime functions are the only ones that
* may be called between 'upcr_startup_init()' and 'upcr_startup_attach()':
*
*      'upcr_mynode()'
*      'upcr_nodes()'
*      'gasnet_getMaxLocalSegmentSize()'
*      'gasnet_getMaxGlobalSegmentSize()'
*      'upcr_getenv()'
*      'upcr_global_exit()'
*
* All other runtime calls are prohibited until after a successful
* 'upcr_startup_attach()'.
*
* 'upcr_startup_init()' may fail with a fatal error and
* implementation-defined message if the nodes of the job cannot be
* successfully bootstrapped.
*
* This function may be called repeatedly, but only the first invocation will
* have any effect.
*/
void upcr_startup_init(int *pargc, char ***pargv,
                      upcr_thread_t static_threadcnt,
                      upcr_thread_t default_pthreads_per_proc,
                      const char * main_name);

#define UPCR_ATTACH_ENV_OVERRIDE      1
#define UPCR_ATTACH_REQUIRE_SIZE     2
#define UPCR_ATTACH_SIZE_WARN        4

/*
* Initializes the UPC runtime's network system, including shared memory
* regions. This function must be called after upcr_startup_init(), but
* before any of the other upcr_startup_ functions.
*
* The 'default_shared_size' parameter gives the default size to request for
* each UPC thread's shared memory region.
*
* The 'default_shared_offset' parameter specifies the minimum distance (in
* bytes) to provide between the current end of the regular C heap (commonly
* provided by sbrk(0)) and the beginning of the shared memory region. On
* some platforms this offset becomes the growth limit for the regular C heap
* (and thus determines how much more memory malloc(), calloc(), etc. can
* return before failing). On most systems, it is irrelevant, and 0 should be
* passed, since using a large offset may limit the size of the shared memory
* region.
*
* Values for 'default_shared_size' and 'default_shared_offset' must be
* multiples of UPCR_PAGESIZE. Both parameters may each be overridden at run
* time if the 'flags' parameter allows it (see below).

```

```

*
* The size and address of the shared region that is created for each node in
* the application can be determined after this call with the
* gasnet_getSegmentInfo() function. The size of the shared segment is
* guaranteed to be no larger than the requested size times the number of
* pthreads on the node (with pthreads==1 if pthreads are not being used).
* The region can be smaller than the requested amount, unless
* UPCR_ATTACH_REQUIRE_SIZE is passed in the 'flags' parameter or the
* UPC_REQUIRE_SHARED_SIZE environment variable is set to a nonempty value.
*
* The 'flags' parameter can contain one or more of the following values (OR
* them together if multiple flags are used):
*
*   UPCR_ATTACH_ENV_OVERRIDE
*   - if passed, the function checks the process' environment for
*     UPC_SHARED_HEAP_SIZE and/or UPC_SHARED_HEAP_OFFSET. If these are
*     set to valid values (a number immediately followed by a 'MB' or
*     'GB', for example '32MB' for 32 megabytes, or '4GB' for 4
*     gigabytes), they override the default_shared_size and
*     default_shared_offset values, respectively.
*
*   UPCR_ATTACH_REQUIRE_SIZE
*   - if this flag is passed, the function will die with an error message
*     printed to stderr if the allocated shared region on any node is
*     smaller than the amount that was asked for times the number of
*     pthreads. Can be overridden at startup by setting the
*     UPC_REQUIRE_SHARED_SIZE environment variable to 'yes' or 'no'.
*
*   UPCR_ATTACH_SIZE_WARN
*   - if this flag is passed, the runtime will issue a warning to stderr
*     if a smaller shared memory segment than requested will be used.
*     Can be overridden at startup by setting the UPC_SIZE_WARN
*     environment variable to 'yes' or 'no'.
*
* If any errors are encountered during upcr_startup_attach, an error message
* is printed and the job is aborted.
*/

void upcr_startup_attach(uintptr_t default_shared_size,
                        uintptr_t default_shared_offset,
                        int flags);

/*
* Struct argument to upcr_startup_spawn.
*/
struct upcr_startup_spawnfuncs {
    void (*pre_spawn_init)();
    void (*per_thread_init)();
    void (*cache_init)(void *start, uintptr_t len);
    void (*heap_init)(void *start, uintptr_t len);
    void (*static_init)(void *start, uintptr_t len);
    int (*main_function)(int argc, char **argv);
};

/*
* Completes runtime initialization, including launching of any additional
* pthreads (if a pthreaded runtime is used), and running of the user's main()
* function (if any).
*
* '*pargc' and '*pargv' will be passed to the 'main_function' in the
* 'spawnfuncs' argument (if it is non-NULL). The 'static_data_size'
* parameter should have a nonzero value if and only if static shared data get
* their own section of the shared memory segment, separate from the shared
* heaps (in Berkeley upc static data are allocated off of the heap; GCCUPC
* uses a separate segment), and this should be the size of the static data
* for each UPC thread. The 'default_cache_size' indicates how much shared
* memory to reserve for caching (by default): since caching is not yet
* implemented, pass 0.
*
* The 'spawnfuncs' parameter is a struct containing pointers to six
* functions.
*
* The 'pre_spawn_init' function, if not NULL, is called first, before any
* pthreads are launched. It can contain any arbitrary initializations that
* should happen only once per-process.
*
* Each of the remaining function pointers is called once on each UPC thread.
*
* The 'per_thread_init' function, if not NULL, is called by each pthread,
* and can contain arbitrary initializations that need to happen on a
* per-pthread basis.
*

```

```

* The 'cache_init' function is called next, but only if caching is being
* used (i.e. if UPCR_USING_CACHING is defined). It may be set to NULL
* otherwise. It must initialize the cache within the given region.
*
* The 'heap_init' function is called next, and must initialize the runtime
* shared heaps. It is passed parameters indicating the starting address and
* length of the region to use for the heap.
*
* The 'static_init' function is then called. It must set up all static data
* for the UPC thread, and is passed the address and length of the segment to be
* used. The length passed is guaranteed to be at least as large as provided in the
* 'static_data_size' parameter, and the locations in the region are guaranteed to
* have lower virtual addresses than the local addresses for any shared data
* with affinity to this thread allocated using the dynamic shared memory
* allocation functions.
*
* Next, a barrier is performed. Finally, if the 'main_function' parameter is
* NULL, the function returns (and upcr_exit() should be used for any program
* exit path, including the end of 'main'). Otherwise 'main_function' is
* called with the command line arguments passed in 'argv' and 'argc' (with a
* new copy made for each pthread if pthreads are used). Again, upcr_exit()
* should be used for any exit paths, except that returns from 'main_function'
* are handled automatically, with the return value used as the program's exit
* code.
*
* If 'main_function' != NULL, this function never returns.
*
* If any errors occur during this function, an error message is printed to
* stderr and the job is terminated.
*
*/
void upcr_startup_spawn(int *pargc, char ***pargv,
                       uintptr_t static_data_size,

/* Runtime shutdown/exit function.
*
* This function should be called as the last program statement for all exit
* paths from a UPC application, with the single exception that the
* 'main_function' used by upcr_startup_spawn() may simply return an integer,
* in which case the behavior is the same as if a call to this function had
* been made with that value.
*
* The behavior of any code called after this function is undefined (i.e. it
* may not execute).
*/
void upcr_exit(int exitcode);

/*****
* Framework for external bootstrapping of the UPC runtime.
*
* The 'bupc_init()' and 'bupc_init_reentrant()' functions allow 'external'
* bootstrapping of the UPC runtime, i.e., initialization of the runtime by
* programs which are not written entirely in UPC, and whose main() does not
* appear in a UPC file.
*
* To provide the full amount of needed data to the runtime, these functions
* require a set of 'magic' global variables to be set by the Berkeley UPC
* linker (upcc).
*****/

/*
* Public, user-accessible function for bootstrapping the Berkeley UPC runtime
* from a non-UPC C or C++ program that does not use pthreads.
*
* A call to this function should be the first statement in main(). The
* semantics of any code appearing before it is implementation-defined (for
* example, it is undefined how many threads of control will run that code, or
* whether stdin/stdout/stderr are functional). The presence of environment
* variables is also not guaranteed, but after this call returns bupc_getenv()
* can be used to retrieve them (regular getenv() is not guaranteed to provide
* them).
*
* The addresses of the command-line parameters must be passed, and it is not
* safe to otherwise refer to them until after this function returns, as it
* may supplement or modify them.
*
* Once bupc_init() has returned, the application may safely call into UPC
* routines. All exit paths from the program should call bupc_exit() as

```

```

* their last program statement.
*
* If any errors are encountered during this function's execution, an error
* message is printed to stderr and the job will be aborted.
*
* This call may register UNIX signal handlers. Client code should not
* register signal handlers or rely on the correct propagation of signals.
*
* This function cannot be used with a pthreaded application. Use
* bupc_init_reentrant() instead.
*
* This function may be called repeatedly, but only the first invocation will
* have any effect.
*
* If used within a hybrid MPI/UPC program, this function also ensures that
* MPI_Init() is called, if needed. MPI_Init() should NOT be called by user
* code if this function is used.
*/
void bupc_init(int *argc, char ***argv);

/*
* A portable version of bupc_init(). A call to the bupc_init_reentrant()
* function will initialize the Berkeley UPC runtime, regardless of whether
* pthreads are used or not.
*
* In addition to the addresses of the regular main() command-line
* parameters, this function takes a function pointer. Calling
* bupc_init_reentrant() will cause all the pthreads known to the UPC runtime
* to be launched, and each of them will then call the 'pmain_func()' with
* their own copy of the command-line parameters. 'pmain_func' may not be
* NULL.
*
* Like with bupc_init(), bupc_exit() should be called at the end of all
* program exit paths, except for returns from 'pmain_func'. If
* 'pmain_func' returns, its return value is used to indicate the exit code
* of the program, and the UPC runtime will exit correctly without an explicit
* call to bupc_exit() being required.
*
* No meaningful code should follow this function call, as it exits before
* returning.
*
* Within pmain_func(), user code may call into UPC routines. It is only safe
* to access UPC routines from the original pthread(s) whose pmain_func() is
* called, however. If additional pthreads are launched by the user
* application, they must not call UPC routines, or behavior is undefined.
*
* Within pmain_func, bupc_getenv() can be used to retrieve values of
* environment variables (regular getenv() is not guaranteed to provide them).
*
* If any errors are encountered during this function's execution, an error
* message is printed to stderr and the job will be aborted.
*
* This call may register UNIX signal handlers. Client code should not
* register signal handlers or rely on the correct propagation of signals.
*
* This function may be called repeatedly, but only the first invocation will
* have any effect.
*
* If used within a hybrid MPI/UPC program, this function also ensures that
* MPI_Init() is called, if needed. MPI_Init() should NOT be called by user
* code if this function is used.
*
* This function can also be used by UPC compilers to bootstrap a UPC job, if
* the user's 'main' function is renamed and passed in as the 'pmain_func'
* parameter.
*/

/* Support for systems which store shared variables in a separate linker
 * section.
 *
 * Some systems (ex: GCC UPC) convert 'shared' static data into a separate
 * linker section. In this case, the values stored in shared pointers are
 * within that linker section (since they are assigned by the linker).
 *
 * To work with Berkeley UPC, the linker section must be mapped into a portion
 * of the shared region provided by gasnet. Also, if pthreads are used, a
 * separate copy of the linker section must exist for each pthread.
 *
 * These requirements are handled by the runtime so long as
 * UPCRL_USING_LINKADDRS is defined, and the beginning/ending addresses of the
 * linker section are provided in 'UPCRL_shared_begin' and 'UPCRL_shared_end'.
 * The runtime uses these addresses to make a copy for each pthread of the
 * linker section. Then, during each shared <=> local address conversion, an
 * offset is used to convert between the linker-assigned address for a given
 * shared pointer and its the address within a pthread's copy of the static
 * data region.
 *
 * On ELF-based systems, the beginning and ending addresses are typically
 * provided by arranging for the UPCRL_shared_begin/end to be the first and
 * last variables in the linker section that the linker sees (on most linker
 * this can be achieved by putting the symbols in separate 'first.o' and
 * 'last.o' object files that are then passed to the linker as the first and
 * last objects on the linker command line).

/*
Shared Memory Accesses
=====
Transfer scalar values to/from shared memory which may or may not be remote

These comments apply to all put/get functions:

Only functions suffixed with '_strict' can be used to implement a strict
operation: all other data movement functions in this specification are
implicitly relaxed.
nbytes should be a compile-time constant whenever possible
nbytes must be >= 0 and has no maximum size, but implementations
will likely optimize for small powers of 2
source and target addresses (both local and shared) are assumed to be properly
aligned for accessing objects of size nbytes
if nbytes extends beyond the current block the results are undefined
destoffset(srcoffset) is an optional positive or negative BYTE offset, which is added to
the address indicated by dest(src) to determine the target(source) address for the put(get) operation
(Useful for puts(gets) with shared structures)
if adding the number of bytes indicated by destoffset(srcoffset) to dest(src) would cause
dest(src) to pass the end of the current block, the result is undefined
If the source and target memory areas overlap (for memory-to-memory transfers) but do not exactly coincide,
the resulting target memory contents are undefined
Implementations are likely to optimize for the important special case of zero destoffset(srcoffset)
*/

/* UPCR_ATOMIC_MEMSIZE() is a macro describing the datatype sizes at which memory accesses
   will be done atomically. Given a datatype width sz (in bytes) it will return non-zero at compile time
   iff a local or shared memory access of exactly sz bytes, to an address aligned by sz bytes, will happen
   atomically with respect to accesses from other threads to the same location.
A non-zero return value for a given size does not guarantee atomicity for smaller sizes
or unaligned accesses of the given size
Some architectures may provide no atomic sizes
UPCR_ATOMIC_MEMSIZE(0) will return the largest atomic size available, or zero if none exists
*/
#define UPCR_ATOMIC_MEMSIZE(sz) ???

/* --- Blocking memory-to-memory puts and gets ---
A call to these functions will block until the transfer is complete,
and the contents of the destination memory are undefined until it completes.
If the contents of the source memory change while the operation is in progress
the result will be implementation-specific.
The '_strict' versions implement strict UPC puts/gets. It is an error for any
nonblocking (relaxed or strict) operation to overlap a strict put/get.
*/
void upcr_put_shared (upcr_shared_ptr_t dest, ptrdiff_t destoffset, const void *src, size_t nbytes);
void upcr_put_pshared(upcr_pshared_ptr_t dest, ptrdiff_t destoffset, const void *src, size_t nbytes);

/* --- Non-blocking operations ---
The following functions provide non-blocking, split-phase memory access to shared data.
All such non-blocking operations require an initiation (put or get) and a subsequent
synchronization on the completion of that operation before the result is guaranteed.
Synchronization of a get operation means the local result is ready to be examined, and
will contain a value held by the shared location at some time in the interval between
the call to the initiation function and the successful completion of the synchronization
(note this specifically allows implementations to delay the underlying read
until the synchronization operation is called, provided they preserve the blocking
semantics of the synchronization function)
Synchronization of a put operation means the source data has been written to the shared location
and get operations issued subsequently by any thread will receive the new value or a
subsequently written value (assuming no other threads are writing the location)
There are two categories of non-blocking operations:

```

```

upcr_handle_t upcr_put_nb_pshared_strict (upcr_pshared_ptr_t dest, ptrdiff_t destoffset,
                                         const void *src, size_t nbytes);
upcr_handle_t upcr_get_nb_pshared_strict(void *dest, upcr_pshared_ptr_t src,
                                         ptrdiff_t srcoffset, size_t nbytes);

/* --- Explicit handle synchronization (for get_nb and put_nb) ---
upcr supports two basic variants of synchronization for non-blocking operations -
trying (polling) and waiting (blocking).
All explicit synchronization functions take one or more upcr_handle_t values
as input and either return an indication of whether the operation has completed
or block until it completes.
*/

/* Single operation explicit synchronization
Synchronize on the completion of a single, particular non-blocking operation
that was initiated by this thread.
upcr_wait_syncnb() blocks until the specified operation has completed
(or returns immediately if it has already completed).
In any case, the handle value is "dead" after upcr_wait_syncnb() returns and
may not be passed to future synchronization operations
upcr_try_syncnb() always returns immediately, with the value 1 if the
operation is complete (at which point the handle value is "dead", and may
not be used in future synchronization operations), or 0 if the operation is
not yet complete and future synchronization is necessary to complete this operation.

upcr_{try,wait}_syncnb_strict() operate just as upcr_{try,wait}_syncnb() do,
but must be used for strict operations (and only for strict operations).

It is legal to pass UPCR_INVALID_HANDLE as input to these functions:
upcr_wait_syncnb{,_strict}(UPCR_INVALID_HANDLE) return immediately and
upcr_try_syncnb{,_strict}(UPCR_INVALID_HANDLE) return 1.

It is an error to pass a upcr_handle_t value for an operation which has already
been successfully synchronized using one of the explicit synchronization functions
and doing so has undefined results
*/
void upcr_wait_syncnb(upcr_handle_t handle)
int upcr_try_syncnb(upcr_handle_t handle)
void upcr_wait_syncnb_strict(upcr_handle_t handle)
int upcr_try_syncnb_strict(upcr_handle_t handle)

/* Multiple operation explicit synchronization
Synchronize on the completion of an array of non-blocking operation handles
(all of which were initiated by this thread).
numhandles specifies the number of handles in the provided array of handles.
requires numhandles >= 0
upcr_wait_syncnb_all() blocks until all the specified operations have completed
(or returns immediately if they have all already completed).
upcr_try_syncnb_all() always returns immediately, with the value 1 if all
the specified operations have completed, or 0 if one or more of the operations
is not yet complete and future synchronization is necessary to complete some
of the operations.

upcr_try_syncnb_all() will modify the provided array to reflect completions -
handles whose operations have completed are overwritten with the value UPCR_INVALID_HANDLE,
and the client may test against this value when upcr_try_syncnb_all() returns 0
to determine which operations are complete and which are still pending.

implementations of upcr_wait_syncnb_all() _may_ modify the provided array to reflect completions,
but this is not required (and not necessarily for the client since it always blocks until all
operations in the list are complete)

It is legal to pass the value UPCR_INVALID_HANDLE in some or all of the array entries,
and both functions will ignore them so those values have no effect on behavior.
If all entries in the array are UPCR_INVALID_HANDLE (or numhandles==0), then
upcr_try_syncnb_all() will return 1.
Note that there are no strict variants, since the UPC memory consistency
model prohibits multiple outstanding strict operations.
*/

void upcr_wait_syncnb_all(upcr_handle_t *, size_t numhandles)
int upcr_try_syncnb_all(upcr_handle_t *, size_t numhandles)

/*
These operate analogously to the syncnb_all variants, except they only
wait/test for at least one operation corresponding to a _valid_ handle in the
provided list to be complete (the valid handles values are all those which are not
UPCR_INVALID_HANDLE).
Specifically, upcr_wait_syncnb_some() will block until at least one of the
valid handles in the list has completed, and indicate the operations that have
completed by setting the corresponding handles to the value UPCR_INVALID_HANDLE.
Similarly, upcr_try_syncnb_some will check if at least one valid handle in the

```

```

    list has completed (setting all completed handles to UPCR_INVALID_HANDLE) and
    return 1 if it detected at least one completion or 0 otherwise (except as below)

Both functions ignore UPCR_INVALID_HANDLE values. If the input list is empty or
consists only of UPCR_INVALID_HANDLE values, upcr_wait_syncnb_some will
return immediately and upcr_try_sync_some will return 1.
*/

void upcr_wait_syncnb_some(upcr_handle_t *, size_t numhandles)
int upcr_try_syncnb_some(upcr_handle_t *, size_t numhandles)

/* --- Non-blocking memory-to-memory, implicit handle (nbi) ---
These calls initiate a non-blocking operation and return "immediately"
the operation must later be completed using a call to one of the implicit sync functions
Once the put version returns, the source memory may safely be overwritten
For a get operation, if the contents of the source memory change while the operation is in progress
the result will be implementation-specific.
The contents of the destination memory address are undefined until a
synchronization completes successfully for the non-blocking operation.
There are no strict nbi operations, as the UPC memory consistency model prohibits multiple
outstanding strict operations.
*/
void upcr_put_nbi_shared (upcr_shared_ptr_t dest, ptrdiff_t destoffset,
                        const void *src, size_t nbytes);

/* --- Implicit handle synchronization (for get_nbi and put_nbi) --- */
/* Synchronize on an implicit list of outstanding non-blocking operations.
These functions implicitly specify a set of non-blocking operations on which to synchronize -
either all outstanding implicit-handle gets initiated by this thread,
all outstanding implicit-handle puts initiated by this thread,
or all outstanding implicit-handle operations (both puts and gets) initiated by this thread
(where outstanding is defined as all those operations which have been initiated
but not yet completed through a successful implicit-handle synchronization).
The wait variants block until all operations in this implicit set have completed
The try variants test whether all operations in the implicit set have completed,
and return 1 if so (or if there are no outstanding implicit-handle operations)
or 0 otherwise
Implicit synchronization functions will synchronize operations initiated within
other function frames by this thread
As with the initiation functions, there are no strict variants here.
*/

int upcr_try_syncnbi_gets();
int upcr_try_syncnbi_puts();
int upcr_try_syncnbi_all();

/* --- Implicit region synchronization --- */
/* In some cases, it may be useful or desirable to initiate a number of non-blocking
shared-memory operations (possibly without knowing how many at compile-time) and
synchronize them at a later time using a single, fast synchronization.
Simple implicit handle synchronization may not be appropriate for this situation if
there are intervening implicit accesses which are not to be synchronized.
This situation could be handled using explicit-handle non-blocking operations and a
list synchronization (e.g. upcr_wait_syncnb_all()), but this may not be desirable
because it requires managing an array of handles (which could have negative cache
effects on performance, or could be expensive to allocate when the size is not known
until runtime).
To handle these cases, we provide "implicit access region" synchronization, described below.
*/

/* upcr_begin_nbi_accessregion() and upcr_end_nbi_accessregion() are used to define an
implicit access region (any code which dynamically executes between the begin and
end calls is said to be "inside" the region)
The begin and end calls must be paired, and may not be nested recursively or the results
are undefined.
It is erroneous to call any implicit-handle synchronization function within the region.
All implicit-handle non-blocking operations initiated inside the region become "associated"
with the abstract region handle being constructed. upcr_end_nbi_accessregion() returns an
explicit handle which collectively represents all the associated implicit-handle operations
(those initiated within the region).
This handle can then be passed to the regular explicit-handle synchronization functions,
and will be successfully synchronized when all of the associated non-blocking
operations initiated in the region have completed.

```

```

    The associated operations cease to be implicit-handle operations, and are _not_ synchronized
    by subsequent calls to the implicit-handle synchronization functions (e.g. upcr_wait_syncnb_all())
    Explicit-handle operations initiated within the region operate as usual and do _not_ become
    associated with the region.
*/

/*
   Shared Memory Bulk Memory Operations
   =====
   Transfer bulk data to/from shared memory which may be remote
   Note these operations all take upcr_shared_ptr_t's (not phaseless ptrs)
   All sizes are specified in BYTES, nbytes >= 0
   Semantics are the same as those specified in the UPC spec
   Implementations will likely optimize for larger values of nbytes
   If the source and target memory areas overlap (but do not exactly coincide),
   the resulting target memory contents are undefined

   The motivation for having memget and memput, separately from the memory ops above:
   - well defined semantics for crossing block boundaries
   - no alignment constraints on the pointers
   - non-blocking memput constrains source memory from changing while operation is
     in progress to avoid a potential buffering copy
   - optimize for large sizes

   Implementor's notes:
   upcr_memset() can be implemented on GASNet using a single small active message, which makes
   it very efficient in terms of network communication
*/
void upcr_memget(void *dst, upcr_shared_ptr_t src, size_t nbytes);

/* ----- */
/*
   Dynamic Memory Allocation:
   =====
   UPC runtime interface to generated code for memory allocation
*/

/* Non-collective operation that allocates nblocks * blocksz bytes in the shared memory area
   with affinity to this thread, and returns a pointer to the new data,
   which is suitably aligned for any kind of variable.
   Requires nblocks >= 0 and blocksz >= 0
   The memory is not cleared or initialized in any way, although it has been properly
   registered with the network system in a way appropriate for the current platform such
   that remote threads can read and write to the memory using upcr shared data transfer operations.
   If insufficient memory is available, the function will print an implementation-defined
   error message and terminate the job.
*/

upcr_shared_ptr_t upcr_local_alloc(size_t nblocks, size_t blocksz);

/* Non-collective operation that allocates nblocks * blocksz bytes spread across the shared memory area
   of 1 or more threads, and returns a pointer to the new data,
   which is suitably aligned for any kind of variable.
   Requires nblocks >= 0 and blocksz >= 0

   The memory is blocked across all the threads as if it had been created by the UPC declaration:

       shared [blocksz] char[nblocks * blocksz] (i.e. both sizes are expressed in bytes).

   Specifically, thread i allocates (at least):

       Max({0} union {0 < n <= nblocks * blocksz | (floor(n-1/blocksz) % THREADS) == i}) bytes.

   More specifically, thread i allocates (at least) this many bytes:

       blocksz * ceil(nblocks/THREADS) if i <= (nblocks % THREADS)
       blocksz * floor(nblocks/THREADS) if i > (nblocks % THREADS)

   Implementor's note: Some implementations may allocate the full (blocksz * ceil(nblocks/THREADS))
   memory on each thread for simplicity, even though less may be required on some threads.

   Note if nblocks == 1, then all the memory will be allocated in the shared memory space
   of thread 0 (and implementations should attempt not to waste space on other threads in this
   common special case).

   In all cases the returned pointer will point to a memory location in the shared memory space
   of thread 0, and any subsequent chunks in the shared space of other threads will be logically
   aligned with this pointer (such that incrementing a shared pointer of the appropriate blocksz
   past the end of a block on one thread will bring it to the start of the next block on the next thread).

   The phase of the returned pointer is set to zero

   The memory is not cleared or initialized in any way, although it has been properly registered
   with the network system in a way appropriate for the current platform such that remote threads
   can read and write to the memory using the upcr shared data transfer operations.
   If insufficient memory is available, the function will print an implementation-defined error
   message and terminate the job.
*/

upcr_shared_ptr_t upcr_global_alloc(size_t nblocks, size_t blocksz);

/* Collective version of upcr_global_alloc() - the semantics are identical to upcr_global_alloc()

```

```

with the following exceptions:
* the function must be called by all threads during the same synchronization phase,
  and all threads must provide the same arguments
* may act as a barrier for all threads, but might not in some implementations
* all threads receive a copy of the result, and the shared pointer values will
  compare equal (according to upcr_isequal_shared_shared()) on all threads
*/

upcr_shared_ptr_t upcr_all_alloc(size_t nblocks, size_t blocksz);

/* Non-collective operation used to deallocate a shared memory region previously allocated
  (but not deallocated) using one of: upcr_local_alloc(), upcr_global_alloc() or upcr_all_alloc().
  If sptr is a null pointer the operation is ignored.
  The shared pointer value passed to upcr_free() must be the same value returned by the
  allocation function that created the region (i.e. it must point to the beginning of the object,
  and for upcr_global_alloc() and upcr_all_alloc() the thread field must indicate thread 0).
  If sptr has been freed by a previous call to upcr_free() or does not point to the beginning of
  a live object in shared memory, the behavior is undefined.

  Note that any thread may call upcr_free() to free a given dynamically-allocated shared object,
  even if that object was created by a call to upcr_local_alloc() from a different thread.

  Also note that memory allocated using upcr_all_alloc() should only be freed by a call to upcr_free()
  from a _single_ thread.
*/

void upcr_free(upcr_shared_ptr_t sptr)

/* ----- */
/*
  Barrier
  =====
  The runtime provides split-phase barrier support
*/

#define UPCR_BARRIERFLAG_ANONYMOUS ???

/* Execute the notification for a split-phase barrier, with a barrier value
  This is a non-blocking operation that completes immediately after noting the barrier value
  No synchronization is performed on outstanding memory accesses (i.e. the
  compiler is responsible for inserting the appropriate syncs to implement
  the null strict reference implied by upc_notify before calling upcr_notify())
  Generates a fatal error if this is the second call to upcr_notify() on this thread
  since the last call to upcr_wait() or the beginning of the program
  flags should be 0 to indicate a normal barrier (which carries the value barrierval)
  or UPCR_BARRIERFLAG_ANONYMOUS to indicate an "anonymous" barrier, where the
  barrierval argument is ignored and the notify automatically "matches" with any
  anonymous or non-anonymous value provided by the notify called on other threads
  Implementation notes:
  check value of thread's notify/wait toggle which records current state of synchronization
  save this thread's barrier value and flags
  increment a counter of local threads that called notify this epoch & return
  last thread on this node to call upcr_notify()
  checks the barrier values calls gasnet_notify() with appropriate flags then resets the counter
*/
void upcr_notify(int barrierval, int flags);

/* Execute the wait for a split-phase barrier, with a barrier value
  This is a blocking operation that returns only after all threads have called upcr_notify()
  No synchronization is performed on outstanding memory accesses (i.e. the
  compiler is responsible for inserting the appropriate syncs to implement
  the null strict reference implied by upc_wait after calling upcr_wait())
  Generates a fatal error if there were no preceding calls to upcr_notify() from this thread,
  or if this is the second call to upcr_wait() since the last call to upcr_notify() on this thread
  Generates a fatal error if flags is not equal to the flags value passed in the preceding
  upcr_notify() call made by this thread
  Generates a fatal error if flags==0 and the supplied barrierval doesn't match the value provided
  in the preceding upcr_notify() call made by this thread
  Generates a fatal error if any two threads passed non-anonymous barrier values which didn't match
  during the notify calls which began this barrier phase

  Implementation notes:
  check and toggle value of thread's notify/wait status which records current state of synchronization
  check that i matches previous value provided by thread in this barrier epoch
  first thread to enter grabs a lock, spin waits until all threads have called notify (counter reset)
  calls gasnet_wait with appropriate flags, (aborts if there is a mismatch reported)
  and signals that wait is complete by writing a barrier_done flag
  all other threads either block on the lock (if they arrive during gasnet_wait) or merely
  see that wait is complete and return the mismatch value
  increment a counter of local threads that called wait this epoch & block (sleep or spin-wait)
  last thread on this node to call upcr_wait calls gasnet_wait(i), then releases the other threads
  when it returns

```

```

*/
void upcr_wait(int barrierval, int flags);

/* upcr_try_wait() functions similarly to upcr_wait(), except that it always returns immediately.
   If the barrier has been notified by all threads, the call behaves as a call to upcr_wait()
   with the same barrierval and flags, and returns the value 1
   If the barrier has not yet been notified by some thread,
   the call is a no-op and returns the value 0
   Note this call is not mandated by the UPC spec, but may be useful for performing purely local
   computation in optimized code or performing system housekeeping duties
*/
int upcr_try_wait(int barrierval, int flags);

/* ----- */
/*
 * Network polling
 * =====
 *
 * The upcr_poll() function explicitly causes the runtime to attempt to make
 * progress on any network requests that may be pending. While many other
 * runtime functions implicitly do this as well (i.e. most of those which call
 * the network layer) this function may be useful in cases where a large amount
 * of time has elapsed since the last runtime call (e.g. if a great deal of
 * application-level calculation is taking place). This function may also be
 * indirectly when a upc_fence is used.
 */
void upcr_poll();

/* ----- */
/*
UPC locks
=====
The following assumes the updates in the UPC spec 1.1 regarding upc locks,
namely:
- upc_lock_t is an opaque shared datatype with incomplete type (prohibits
  statically-allocated upc_lock_t objects)
- upc_lock_init() is no longer necessary or useful and is removed
- upc_lock_free() is added to allow users to free dynamically-allocated locks
- UPC locks are _not_ recursive (a thread must not attempt to re-acquire a lock it already owns)

similar to upc_lock_t, the runtime lock datatype is totally opaque and
always manipulated through upcr_shared_ptr_t pointers, which must NEVER be
dereferenced by generated code
this spec intentionally doesn't even provide a name or size for the lock datatype
the shared pointer returned by the lock allocation routines has reference semantics,
(i.e. copying the pointer yields a reference to the same lock)
but otherwise need not even be a real pointer. In other words, the thread affinity
and addrfield components of these shared pointers is completely undefined,
so casting them to a local pointer on _any_ thread may yield a pointer value which
doesn't point to a valid memory address (or points to a random object)
this allows implementations which (for example) store an integer lock identifier
in the address field rather than a true pointer
*/

/* non-collective operation (intended to be called by a single thread)
   which dynamically allocates and initializes a lock,
   and returns a upcr_shared_ptr_t which references that lock.
   If insufficient resources are available, the function will print an implementation-defined
   error message and terminate the job.
*/
upcr_shared_ptr_t upcr_global_lock_alloc();

/* collective operation which dynamically allocates and initializes a lock,
   and returns a upcr_shared_ptr_t which references that lock.
   * the function must be called by all threads during the same synchronization phase,
   * may act as a barrier for all threads, but might not in some implementations
   * all threads receive a copy of the result, and the shared pointer values will
   compare equal (according to upcr_isequal_shared_shared()) on all threads
   If insufficient resources are available, the function will print an implementation-defined
   error message and terminate the job.
*/
upcr_shared_ptr_t upcr_all_lock_alloc();

/* block until the referenced lock can be acquired by this thread
   if no other thread is currently holding or contending for the referenced lock,
   this operation must return within a bounded amount of time
   implementations should attempt to provide fairness in the presence of
   contention for this lock, but this property is not required
   if lockptr does not reference a valid lock object (i.e. one previously allocated by
   upcr_global_lock_alloc() or upcr_all_lock_alloc() and not deallocated using
   upcr_lock_free()) then the results are undefined
   if the current thread is already holding the referenced lock, the result is undefined

```

```

    (although implementations are recommended to print a useful error message and abort)
*/
void upcr_lock(upcr_shared_ptr_t lockptr);

/* attempt to acquire the referenced lock without blocking
the operation always returns immediately, with the value 1 if the lock was
successfully acquired, or with the value 0 if the lock could not be acquired at this time
if no other thread is currently holding or contending for the referenced lock,
repeated calls to this operation will eventually succeed within a bounded amount of time
if lockptr does not reference a valid lock object then the results are undefined
if the current thread is already holding the referenced lock, the result is undefined
(although implementations are encouraged to print a useful error message and abort)
*/
int upcr_lock_attempt(upcr_shared_ptr_t lockptr);

/* unlock the referenced lock
this operation releases the referenced lock, which must have been previously locked
by this thread using upcr_lock(), or a successful call to upcr_lock_attempt()
(otherwise the results are undefined)
if lockptr does not reference a valid lock object then the results are undefined
this operation always completes within a bounded amount of time
implementations are encouraged to detect violations to the locking semantics
(e.g. unlock with no matching lock) but this is not required
*/
void upcr_unlock(upcr_shared_ptr_t lockptr);

/* free a lock - non-collective operation
this call (always made from a single thread) releases any system resources
associated with the referenced lock and makes the lock object "invalid" for all threads
the lock need not have been explicitly created by the current thread (i.e. it may have
been created by a call to upcr_global_lock_alloc() on a separate thread and passed to this one)
any subsequent calls from any thread using this invalidated lock object have undefined effects
if lockptr does not reference a valid lock object then the results are undefined
this operation always completes within a bounded amount of time
repeated calls to upcr_lock_free(upcr_global_lock_alloc()) must succeed indefinitely
(i.e. it must actually reclaim any associated resources)
the call will succeed immediately regardless of whether the referenced lock is currently
unlocked or currently locked (by any thread)
*/
void upcr_lock_free(upcr_shared_ptr_t lockptr);

/* ----- */
/* Statically-allocated user variables
* =====
* The following interfaces provide portable support for statically-allocated user variables
* (shared and unshared, scalar and array)
*/

/*
* Thread-Local Data (TLD)
* =====
* Thread-local data (TLD) is defined to be any NON-shared, statically-allocated
* (i.e. not automatic lifetime) objects declared in UPC source files, namely non-shared
* file-scope (global) objects or static local variables (block-scope TLD).
* TLD must be declared and accessed specially by generated code to ensure correct operation
* across the variety of platforms implementing the UPC runtime.
*
* The macros below must be used to declare all TLD - global or static user unshared
* variables (unless they are declared with 'extern', or are located in a
* regular C file (such as a header file with a name ending in '.h'), since if
* pthreads are used, these variables will need to be made thread-specific.
* Static variables need to be transform into global variables before this
* macro can be used (and their names should be mangled to avoid name
* collisions).
*
* Since uses of these macros are intended to be filterable by tools like
* grep, they must be used at the start of a new line, and their contents
* cannot contain line breaks.
*/

/* UPCR_TLD_DEFINE(name, initval, size) must be used when declaring
* unshared global/static variables that the user has initialized. The
* macro takes the variable name of the value, and the size (in bytes, as a
* single literal number--'sizeof', expressions like '3 + 4', etc., are not
* allowed). So the UPC compiler should transform
*
*     int foo = 5;
*
* on a platform with 4 byte integers into
*
*     int
*     UPCR_TLD_DEFINE(foo, 4) = 5;

```

```

*
* Unshared pointers to shared types (i.e. thread local variables
* with type upcr_shared_ptr_t or upcr_pshared_ptr_t) should be initialized
* with UPCR_INITIALIZED_{P}SHARED rather than the value the user specified.
*
* The full type of the variable must precede the macro, and so arrays and
* function pointers must use a typedef. For instance,
*
*     int natural_nums[3] = { 1, 2, 3};
*     void (*int_taker)(int) = &print_int;
*
* Would become
*
*     typedef int _type_natural_nums[3];
*     _type_natural_nums
*     UPCR_TLD_DEFINE(natural_nums, 12) = { 1, 2, 3 };
*
*     typedef void (*_type_int_taker)(int);
*     _type_int_taker
*     UPCR_TLD_DEFINE(int_taker, 4) = &print_int;
*
* For variables that are not explicitly initialized by the user,
* UPCR_TLD_DEFINE_TENTATIVE(name, size) must be used. The macro
* works the same way as UPCR_TLD_DEFINE, except that it should not be
* followed by "= initializer_expr."
*
* For more information on the uses of these macros, and the treatment of
* thread-local data generally, see the web page on "static user data" in the
* Runtime documentation on the Berkeley UPC web site.
*/

#define UPCR_TLD_DEFINE(name, size)
#define UPCR_TLD_DEFINE_TENTATIVE(name, size)

/* UPCR_TLD_ADDR: retrieve the address of the current thread's representative
   of the TLD variable with the given name (name must be a simple identifier)
   address is returned as a (void *) and should be cast to the proper type before use
*/
#define UPCR_TLD_ADDR(name) ???

/* Example usage:
   int x = *(int*)UPCR_TLD_ADDR(foo);
   *(int*)UPCR_TLD_ADDR(foo) = 100;
   ((int*)UPCR_TLD_ADDR(natural))[2] = 27;
Implementors note:
   UPCR_TLD_ADDR() returns an address rather than an l-value because some planned
   implementations of TLD may not have the TLD type information available
   (TLD will just be opaque bytes in a special data segment)
*/

/*
   Statically-allocated Shared Data (SSD)
   =====
   Statically-allocated Shared Data (SSD) is defined to be any shared,
   statically-allocated (i.e. not automatic lifetime) objects declared in UPC
   source files, namely any shared file-scope (global) objects or static local
   variables (block-scope SSD).

   All SSD is allocated and initialized dynamically at runtime, instead of being
   truly statically allocated (since on most platforms network-addressable memory
   can not be assigned at compile time, and must be dynamically allocated). The
   basic idea is the compiler replaces each SSD declaration with a
   upcr_shared_ptr or upcr_pshared_ptr that will point to the relevant data item
   at runtime (all SSD access operations must be modified appropriately to
   traverse the extra level of indirection). The compiler also adds an
   allocation and an initialization function for each UPC file it compiles, in
   which all SSD declared in the file is allocated and initialized (some
   thread-local data initializations may also be performed there).

   The functions listed below should only be used in these per-file startup
   allocation/initialization routines. For more information on the naming
   conventions for these functions, the content that should go in them, and the
   framework that calls them, refer to the "Handling Static Data in the UPC
   Runtime" document (available in the documentation section of the Berkeley UPC
   website at http://upc.lbl.gov).
*/

/*
* These values are guaranteed to be defined by every shared pointer
* representation. UPCR_INITIALIZED_{P}SHARED should be used by the compiler
* to initialize all upcr_shared_ptr_t and upcr_pshared_ptr_t's that represent

```

```

* shared variables the user defines with an initial value (if the user does
* not provide a value, do not provide any value for the upcr_{p}shared_ptr,
* either).  UPCR_NULL_{P}SHARED should be used to initialize
* upcr_{p}shared_ptr's that represent unshared pointers to shared data that
* the user explicitly initialized to NULL.

/*
* Allocates the specified amount of memory for each shared pointer in the
* array of info structs.
*
* Only performs a given allocation if the memory has not already been allocated
* for the pointer.  If the pointer was not initialized (i.e., is equal to 0
* instead of UPCR_INITIALIZED_SHARED), any memory allocated is also memset
* to 0.
*
* This function must be called by all threads collectively (like
* upc_all_alloc, etc.).  The function does not guarantee that all threads
* will have received the data when any particular thread
* returns from the call (i.e. it does not guarantee a barrier is performed
* after initialization).  The function does guarantee that it may be called
* repeatedly without the need for client barrier calls to be placed in
* between the calls.
*
* See the upcr_startup_shalloc_t struct definition for options affecting how

```

```

* memory is allocated.
*
*/

/*
* Allocates the specified amount of memory for each phaseless shared pointer
* in the array of info structs.
*
* Only performs a given allocation if the memory has not already been allocated
* for the pointer. If the pointer was not initialized (i.e., is equal to 0
* instead of UPC_INITIALIZED_PSHARED), any memory allocated is also memset
* to 0.
*
* This function must be called by all threads collectively (like
* upc_all_alloc, etc.). When the function returns, the shared pointers
* pointed to by 'infos' will be initialized to the correct shared memory
* location on all UPC threads.
*
* See the upcr_startup_shalloc_t struct definition for options affecting how
* memory is allocated.
*/
void upcr_startup_pshalloc(upcr_startup_pshalloc_t *infos, size_t count);

/*
* Information for a single dimension of a shared array initialization.
*
*      local_elems      // Number of elements in local init array's dimension
*      shared_elems     // Number of elements in shared array's dimension
*      mult_by_threads  // Nonzero if shared array's dimension should be
*                      // multiplied by THREADS
*
* Note that the UPC language specification mandates that for a dynamic
* translation environment (i.e. one in which THREADS is not a compile-time
* constant) only one dimension of a shared array can contain THREADS, and it
* can only be used once in that dimension, to multiply a constant size.
*/

typedef struct upcr_startup_arrayinit_diminfo {
    size_t local_elems;
    size_t shared_elems;
    int    mult_by_threads;
} upcr_startup_arrayinit_diminfo_t;

/*
* Initializes a shared array from a local array, or to 0s if NULL is passed
* for the local array.
*
* This function is used to copy initial values from a local array (generated
* by the UPC compiler) that contains any initial values provided by the user.
* The local array does not need to have the same size as the shared array
* (indeed, if the shared array contains THREADS in one of its dimensions, its
* size is not even knowable at compile time). It does, however, need to have
* the same number of dimensions as the shared array, and the same element
* size. All values in the shared array that do not have corresponding values
* in the local array are memset to 0.
*
* The function takes the addresses of the shared and local arrays, a pointer
* to an array of structures (each of which describes a single dimension of
* the array), a count of the number of dimensions in the array, the size (in
* bytes) of the array's element type, and the blocking factor of the array
* (as a number of elements).
*
* If NULL is passed for the local array address, all local array parameters
* will be ignored, and the function will simply set all elements of the
* shared array to 0.
*
* Here is an example:
*
* // in UPC program
*
* shared [5] int j[3][4][2*THREADS] = {
*     {
*         { 1, 2 },
*         { 3, 4 },
*         { 5, 6 },
*         { 1, 2, 3, 4, 5 } // the user may specify extra elems if THREADS
*                          // is part of the dimension
*     }
* };

```

```

* Here the user has only provided a small subset of the initial values in the
* array (even disregarding the THREADS in the final dimension). The UPC
* compiler should place the initial values into a [1][4][5] array, and then
* setup and call the initialization function:
*
* // output .c file, at file scope
*
* upcr_shared_ptr_t j = UPCR_INITIALIZED_SHARED;
*
* int j_initarray[1][4][5] = {
*     {
*         { 1, 2 },
*         { 3, 4 },
*         { 5, 6 },
*         { 1, 2, 3, 4, 5 }
*     }
* };
*
* upcr_startup_arrayinit_diminfo_t j_diminfos[] = {
*     { 1, 3, 0 },
*     { 4, 4, 0 },
*     { 5, 2, 1 }
* };
*
* // In initialization function
*
* upcr_startup_initarray(&j, j_initarray, j_diminfos, 3, sizeof(int), 5);
*
* This function must be called collectively by each UPC thread for each array,
* in the same order and with the same arguments.
* The function does not guarantee that all threads will have completed their
* initializations when any particular thread returns from the call (i.e. it
* does not guarantee a barrier is performed after initialization).
*
* Implementation notes:
* -----
*
* For efficiency, each thread should only copy elements that belong to its
* portion of the shared array, so the function should not cause any network
* traffic.
*
* To save space, the local array's dimensions should only be as large
* as needed to contain all the initial values specified by the user.
*/
